

Evaluating scoring streaks and game excitement using in-match trend estimation

Claus Thorn Ekstrøm and Andreas Kryger Jensen March 24th 2021

Biostatistics, Department of Public Health University of Copenhagen

Roadmap

- 1. Introduction
- 2. Latent dynamics GP Regression
- 3. The 2019–2020 NBA season
- 4. Conclusion

Introduction

How it all started

Dear sports-analytics-enthusiastic colleagues,

Today I want to make you aware of yet another call for a Special Issue on Statistics in Sports in the AStA Advances in Statistical Analysis journal (A Journal of the German Statistical Society) which Dominik Liebl and I are currently hosting as guest editors:

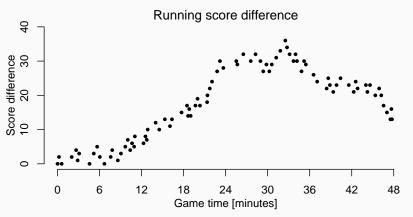

https://www.springer.com/journal/10182/updates/17805238

We are looking forward to receiving high quality submission from at least some of you until 31 October 2020. :-)

All the best, take care and stay safe, Dominik & Andreas

Motivating example

Game development in the final match of the NBA 2019–2020 season between Los Angeles Lakers and Miami Heat at October 11, 2020. Positive values \Rightarrow LA Lakers are leading.

How exciting was this match?

Latent dynamics GP Regression

The generative model of GP regression with data $\mathcal{D}_m = (D_m(t_{mi}), t_{mi})_{i=1}^{n_m}$ is given hierarchically as

$$\mathbf{\mathscr{E}}_{m} \mid \mathbf{\Psi}_{m}, \mathbf{t}_{m} \sim H(\mathbf{\mathscr{E}}_{m} \mid \mathbf{\Psi}_{m})$$

$$d_{m}(t) \mid \mathbf{\mathscr{E}}_{m} \sim \mathcal{GP}(\mu_{\beta_{m}}(t), C_{\boldsymbol{\theta}_{m}}(s, t))$$

$$D_{m}(t_{mi}) \mid d_{m}(t_{mi}), t_{mi}, \mathbf{\mathscr{E}}_{m} \stackrel{iid}{\sim} N\left(d_{m}(t_{mi}), \sigma_{m}^{2}\right)$$

The generative model of GP regression with data $\mathcal{D}_m = (D_m(t_{mi}), t_{mi})_{i=1}^{n_m}$ is given hierarchically as

$$\mathbf{\mathcal{X}}_{m} \mid \mathbf{\Psi}_{m}, \mathbf{t}_{m} \sim H(\mathbf{\mathcal{X}}_{m} \mid \mathbf{\Psi}_{m})$$

$$d_{m}(t) \mid \mathbf{\mathcal{X}}_{m} \sim \mathcal{GP}(\mu_{\boldsymbol{\beta}_{m}}(t), C_{\boldsymbol{\theta}_{m}}(s, t))$$

$$D_{m}(t_{mi}) \mid d_{m}(t_{mi}), t_{mi}, \mathbf{\mathcal{X}}_{m} \stackrel{iid}{\sim} N\left(d_{m}(t_{mi}), \sigma_{m}^{2}\right)$$

By linearity of differentiation and the properties of the Gaussian distribution we may augment the latent space as

$$\begin{bmatrix} d_m(s) \\ d'_m(t) \\ d''_m(u) \end{bmatrix} | \, & \qquad & \mathcal{GP} \left(\begin{bmatrix} \mu_{\boldsymbol{\beta}_m}(s) \\ \mu'_{\boldsymbol{\beta}_m}(t) \\ \mu''_{\boldsymbol{\beta}_m}(u) \end{bmatrix}, \begin{bmatrix} C_{\boldsymbol{\theta}_m}(s,s') & \partial_2 C_{\boldsymbol{\theta}_m}(s,t) & \partial_2^2 C_{\boldsymbol{\theta}_m}(s,u) \\ \partial_1 C_{\boldsymbol{\theta}_m}(t,s) & \partial_1 \partial_2 C_{\boldsymbol{\theta}_m}(t,t') & \partial_1 \partial_2^2 C_{\boldsymbol{\theta}_m}(t,u) \\ \partial_1^2 C_{\boldsymbol{\theta}_m}(u,s) & \partial_1^2 \partial_2 C_{\boldsymbol{\theta}_m}(u,t) & \partial_1^2 \partial_2^2 C_{\boldsymbol{\theta}_m}(u,u') \end{bmatrix} \right)$$

(if the derivatives exist - no Ornstein-Uhlenbeck for you, Sir!)

Inference about the latent processes is given by the posterior

$$\begin{bmatrix} d_m(s) \\ d'_m(t) \\ d''_m(u) \end{bmatrix} \mid \mathcal{D}_m, \textcircled{2}_m \sim \mathcal{GP} \left(\begin{bmatrix} \mu_{d_m}(s) \\ \mu_{d'_m}(t) \\ \mu_{d''_m}(u) \end{bmatrix}, \begin{bmatrix} \Sigma_{d_m}(s,s') & \Sigma_{d_m d'_m}(s,t) & \Sigma_{d_m d''_m}(s,u) \\ \Sigma_{d'_m d_m}(t,s) & \Sigma_{d'_m}(t,t') & \Sigma_{d'_m d''_m}(t,u) \\ \Sigma_{d''_m d_m}(u,s) & \Sigma_{d''_m d'_m}(u,t) & \Sigma_{d''_m}(u,u') \end{bmatrix} \right)$$

Inference about the latent processes is given by the posterior

$$\begin{bmatrix} d_m(s) \\ d'_m(t) \\ d''_m(u) \end{bmatrix} \mid \mathcal{D}_m, \textcircled{2}_m \sim \mathcal{GP} \left(\begin{bmatrix} \mu_{d_m}(s) \\ \mu_{d'_m}(t) \\ \mu_{d''_m}(u) \end{bmatrix}, \begin{bmatrix} \Sigma_{d_m}(s,s') & \Sigma_{d_m d'_m}(s,t) & \Sigma_{d_m d''_m}(s,u) \\ \Sigma_{d'_m d_m}(t,s) & \Sigma_{d'_m}(t,t') & \Sigma_{d'_m d''_m}(t,u) \\ \Sigma_{d''_m d_m}(u,s) & \Sigma_{d''_m d'_m}(u,t) & \Sigma_{d''_m}(u,u') \end{bmatrix} \right)$$

Where the components evaluated at any t^* are given by

$$\begin{split} \mu_{d_{m}}(\mathbf{t}^{*}) &= \mu_{\beta_{m}}(\mathbf{t}^{*}) + C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \left(\mathbf{D}_{m} - \mu_{\beta_{m}}(\mathbf{t}_{m}) \right) \\ \mu_{d_{m}'}(\mathbf{t}^{*}) &= \mu_{\beta_{m}'}'(\mathbf{t}^{*}) + \partial_{1}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \left(\mathbf{D}_{m} - \mu_{\beta_{m}}(\mathbf{t}_{m}) \right) \\ \mu_{d_{m}''}(\mathbf{t}^{*}) &= \mu_{\beta_{m}'}'(\mathbf{t}^{*}) + \partial_{1}^{2}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \left(\mathbf{D}_{m} - \mu_{\beta_{m}}(\mathbf{t}_{m}) \right) \\ \Sigma_{d_{m}}(\mathbf{t}^{*}, \mathbf{t}^{*}) &= C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}^{*}) - C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}^{*}) \\ \Sigma_{d_{m}'}(\mathbf{t}^{*}, \mathbf{t}^{*}) &= \partial_{1}\partial_{2}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}^{*}) - \partial_{1}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \partial_{2}C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}^{*}) \\ \Sigma_{d_{m}'}(\mathbf{t}^{*}, \mathbf{t}^{*}) &= \partial_{1}^{2}\partial_{2}^{2}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}^{*}) - C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \partial_{2}^{2}C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}^{*}) \\ \Sigma_{d_{m}d_{m}'}(\mathbf{t}^{*}, \mathbf{t}^{*}) &= \partial_{2}^{2}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}^{*}) - C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \partial_{2}^{2}C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}^{*}) \\ \Sigma_{d_{m}d_{m}''}(\mathbf{t}^{*}, \mathbf{t}^{*}) &= \partial_{1}^{2}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}^{*}) - C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \partial_{2}^{2}C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}^{*}) \\ \Sigma_{d_{m}d_{m}''}(\mathbf{t}^{*}, \mathbf{t}^{*}) &= \partial_{1}^{2}C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}^{*}) - C_{\theta_{m}}(\mathbf{t}^{*}, \mathbf{t}_{m}) \left(C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}_{m}) + \sigma_{m}^{2} I \right)^{-1} \partial_{2}^{2}C_{\theta_{m}}(\mathbf{t}_{m}, \mathbf{t}^{*}) \end{split}$$

Trend Direction Index (TDI)

$$TDI_{m}(t \mid \mathcal{E}_{m}) = P\left(d'_{m}(t) > 0 \mid \mathcal{D}_{m}, \mathcal{E}_{m}\right)$$
$$= \frac{1}{2} + \frac{1}{2} \operatorname{Erf}\left(\frac{\mu_{d'_{m}}(t)}{2^{1/2} \Sigma_{d'_{m}}(t, t)^{1/2}}\right)$$

Excitement Trend Index

$$\begin{aligned} \text{ETI}_{m} \mid & \bigstar_{m} = \mathbb{E} \left[\# \left\{ t \in \mathcal{I}_{m} : d'_{m}(t) = 0 \right\} \mid \mathcal{D}_{m}, & \bigstar_{m} \right] \\ &= \int_{\mathcal{I}_{m}} \int_{-\infty}^{\infty} |v| \, f_{d'_{m}(t), d''_{m}(t)}(0, v \mid \mathcal{D}_{m}, & \bigstar_{m}) \mathrm{d}v \mathrm{d}t \\ &= \int_{\mathcal{I}_{m}} d \text{ETI}_{m}(t \mid & \bigstar_{m}) \mathrm{d}t \end{aligned}$$

Excitement Trend Index

?

$$d\mathrm{ETI}_m(t\mid \boldsymbol{\mathscr{Z}}_m) = \lambda_m(t)\phi\left(\frac{\mu_{d_m'}(t)}{\Sigma_{d_m'}(t,t)^{1/2}}\right)\left(2\phi\left(\zeta_m(t)\right) + \zeta_m(t)\operatorname{Erf}\left(\frac{\zeta_m(t)}{2^{1/2}}\right)\right)$$

$$\lambda_m(t) = \frac{\sum_{d'_m}(t,t)^{1/2}}{\sum_{d'_m}(t,t)^{1/2}} \left(1 - \omega_m(t)^2\right)^{1/2}, \quad \omega_m(t) = \frac{\sum_{d'_m d'_m}(t,t)}{\sum_{d'_m}(t,t)^{1/2} \sum_{d''_m}(t,t)^{1/2}}$$
$$\zeta_m(t) = \frac{\mu_{d'_m}(t) \sum_{d'_m}(t,t)^{1/2} \omega_m(t) \sum_{d'_m}(t,t)^{-1/2} - \mu_{d''_m}(t)}{\sum_{d'_m}(t,t)^{1/2} \left(1 - \omega_m(t)^2\right)^{1/2}}$$

Estimation

$$\mu_{\beta_m}(t) = \beta_m, \quad C_{\theta_m}(s, t) = \alpha_m^2 \exp\left(-\frac{(s - t)^2}{2\rho_m^2}\right)$$

The hyper-parameters are given the following prior distribution

$$H(\mathscr{F}_m \mid \Psi_m) = H(\beta_m \mid \Psi_{\beta_m})H(\alpha_m \mid \Psi_{\alpha_m})H(\rho_m \mid \Psi_{\rho_m})H(\sigma_m \mid \Psi_{\sigma_m})$$

with

$$\beta_m \sim T_4\left(\widehat{\beta_m^{\mathrm{ML}}}, 5\right), \ \alpha_m \sim T_4^+\left(\widehat{\alpha_m^{\mathrm{ML}}}, 5\right), \ \rho_m \sim T_4^+\left(\widehat{\rho_m^{\mathrm{ML}}}, 5\right), \ \sigma_m \sim T_4^+\left(\widehat{\sigma_m^{\mathrm{ML}}}, 5\right)$$

Super-script ML indicates the marginal maximum-likelihood estimate (empirical Bayes).

Empirical bayes

To find the empirical Bayes estimate of the hyper-parameters we maximize the marginal log-likelihood function. This can be written as

$$\log L(\mathcal{E}_m \mid \mathcal{D}_m) \propto -\frac{1}{2} \log |C_{\boldsymbol{\theta}_m}(\mathbf{t}_m, \mathbf{t}_m) + \sigma_m^2 I|$$

$$-\frac{1}{2} (\mathbf{D}_m - \mu_{\boldsymbol{\beta}_m}(\mathbf{t}_m))^T \left[C_{\boldsymbol{\theta}_m}(\mathbf{t}_m, \mathbf{t}_m) + \sigma_m^2 I \right]^{-1} (\mathbf{D}_m - \mu_{\boldsymbol{\beta}_m}(\mathbf{t}_m))$$

The solution $\mathcal{E}_m^{\mathrm{ML}} = \arg\sup_{\mathcal{E}} \log L(\mathcal{E} \mid \mathcal{D}_m)$ can be obtained by numerical optimization.

Our model is implemented in Stan and for each match we ran 4 chains for 50,000 iterations with half of them for warm-up. Output: 2292 gigabyes of posterior data.

11

The 2019–2020 NBA season

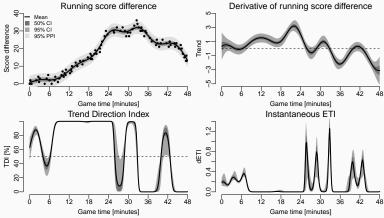

The 2019–2020 NBA season

We applied our method for all 1143 matches from the 2019–2020 NBA basketball season.

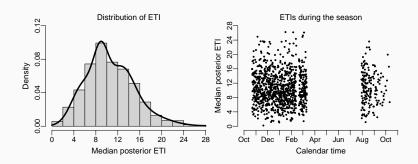

We disregarded overtime.

Final match between LA Lakers and Miami Heat

An algorithm for collapsing a factor into sub-groups

If I were to go see an exciting match — who should I watch?

An algorithm for collapsing a factor into sub-groups

If I were to go see an exciting match — who should I watch?

Cluster teams based on their median posterior ETI.

Compute the RMSEP $_{\text{LOO-CV}}^{C=c}$ where c is the number of subgroups considering all possible partitions of the 30 teams. Essentially a bunch of one-way ANOVAs

$$\mathrm{RMSEP}_{\mathrm{LOO-CV}}^{C=2} = 4.493$$

$$RMSEP_{LOO-CV}^{C=3} = 4.49$$

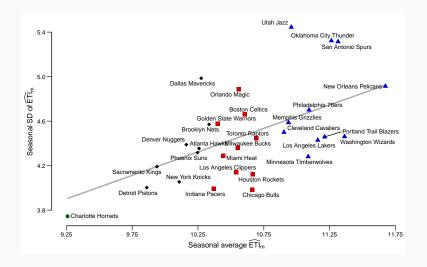

$$RMSEP_{LOO-CV}^{C=4} = 4.489$$

$$RMSEP_{LOO-CV}^{C=5+} = 4.489$$

Team specific seasonal SD vs. average ETIs

Conclusion

Conclusion

- The trender enables in-game and postgame evaluations about the underlying trends in scoring patterns.
- ETI is the expected number of monotonicity changes which team appears stronger. High numbers good.

Future ideas:

• Use a weighted ETI to weigh the ETI higher towards the end of the game — or lower if one team is far ahead.

Also: have cemented our position as sports-analytics-enthusiasts.
